

Meth

Methamphetamine, or meth, is extremely dangerous

- Meth is extremely addictive and can corner a user into addiction quite quickly.
- It's also relatively cheaper than other street drugs due to the ease of making it. Makeshift meth labs can use a slew of household, over-the-counter ingredients to create the odorless, bitter, white crystalline powder.
- Meth masquerades under the street names of speed, ice, glass, crank and chalk and can be taken using a number of methods.
- It can be smoked, injected, snorted or ingested. Not only do users quickly need greater quantities of meth to achieve the same high they did during their earlier uses, but they also need more meth just to combat the agonizing withdrawal symptoms. Treating methamphetamine addiction is certainly possible, but requires the highest level of care and often medical supervision is necessary.
